Normal Breast Tissue Implanted into Athymic Nude Mice Identifies Biomarkers of the
Effects of Human Pregnancy Levels of Estrogen. Rognvald N. Blance, Andrew H. Sims,
Elizabeth Anderson, Anthony Howell and Robert B. Clarke .................................................................257
About the Cover
The cover displays a near-infrared photographic image produced by a small-animal fluorescence imaging system (Olympus, Tokyo, Japan) of cathepsin expression marked by Prosense in the small bowel of a mouse. Cathepsin proteins are cysteine proteases and have been implicated in cancer pathogenesis. Prosense is a non-fluorescent macromolecule that is activated and becomes fluorescent through cleavage by cathepsins. Activated Prosense shows up in the adenoma (where false-colored red and orange reflect areas of greater near-infrared signal intensity) but not in the surrounding normal mucosa (where false-colored violet and blue reflect areas of less signal). Therefore, cathepsin activity occurred selectively in the adenoma site. Increased expression of cathepsins B and D also occurred in the plasma of adenoma-bearing mice and in mouse adenoma tissue assessed immunohistochemically. See article by Hung et al. (beginning on page 224) for more information.
